## **Fast-twitch glycolytic skeletal muscle is predisposed to age-induced impairments in mitochondrial function**

Jacobs, Robert A ; Díaz, Víctor ; Soldini, Lavinia ; Haider, Thomas ; Thomassen, Martin ; Nordsborg, Nikolai B ; Gassmann, Max ; Lundby, Carsten

**Abstract:** The etiology of mammalian senescence is suggested to involve the progressive impairment of mitochondrial function; however, direct observations of age-induced alterations in actual respiratory chain function are lacking. Accordingly, we assessed mitochondrial function via high-resolution respirometry and mitochondrial protein expression in soleus, quadriceps, and lateral gastrocnemius skeletal muscles, which represent type 1 slow-twitch oxidative muscle (soleus) and type 2 fast-twitch glycolytic muscle (quadriceps and gastrocnemius), respectively, in young (10-12 weeks) and mature (74-76 weeks) mice. Electron transport through mitochondrial complexes I and III increases with age in quadriceps and gastrocnemius, which is not observed in soleus. Mitochondrial coupling efficiency during respiration through complex I also deteriorates with age in gastrocnemius and shows a tendency ( $p = .085$ ) to worsen in quadriceps. These data demonstrate actual alterations in electron transport function that occurs with age and are dependent on skeletal muscle type.

**Short running page headline:** Skeletal muscle mitochondrial function with aging

## 1 Summary (145)

2 The etiology of mammalian senescence is suggested to involve the progressive impairment of  
3 mitochondrial function, however direct observations of age-induced alterations in actual  
4 respiratory chain function are lacking. Accordingly we assessed mitochondrial function via  
5 high-resolution respirometry and mitochondrial protein expression in soleus (SOL), quadricep  
6 (QUAD), and lateral gastrocnemius (GAST) skeletal muscles, which represent type 1 slow  
7 twitch oxidative (SOL), and type 2 fast twitch glycolytic muscle (QUAD and GAST),  
8 respectively, in young (10-12 wk) and mature (74-76 wk) mice. Electron transport through  
9 mitochondrial complexes I and III increase with age in QUAD and GAST, which is not  
10 observed in SOL. Mitochondrial coupling efficiency during respiration through complex I  
11 also deteriorates with age in GAST and shows a tendency ( $p = 0.085$ ) to worsen in QUAD.  
12 This data demonstrates actual alterations in electron transport function that occur with age and  
13 are dependent on skeletal muscle type.

1  
2  
3 **1 Introduction**

4 An inherent flaw of the bioenergetic reliance on aerobic metabolism to sustain life is the  
5 corollary oxidant production (1), and consequently mitochondria serve as the primary source  
6 of *in vivo* oxidant production (2-5). Mitochondrial-derived reactive oxygen species (ROS) are  
7 largely accounted for by superoxide ( $O_2^-$ ) production into the mitochondrial matrix at  
8 mitochondrial complex I (CI) (6-8) and into both the matrix and mitochondrial  
9 intermembrane space at mitochondrial complex III (CIII) (9-14). The progression of ROS  
10 production beyond hormetic concentrations precipitates deleterious and indiscriminate  
11 oxidation of nucleic acids, proteins, and lipids (5, 15, 16). These pernicious effects then  
12 correspondingly impair mitochondrial function, which result in greater oxidant production,  
13 and so on leading to a “vicious cycle” and eminent cellular demise (4, 15, 17). The  
14 mitochondrial theory of aging asserts that the biological aging process is facilitated by this  
15 progressive accrual of mitochondrial (mt) DNA damage and reciprocal decline of  
16 mitochondrial function (18). While evidence of increasing mtDNA alteration with age is  
17 supported by the literature, data suggestive of an impairment of mitochondrial function with  
18 aging are inconsistent.

19  
20 Senescence corresponds with mounting indications of nuclear and mtDNA damage in both  
21 humans and animals (19-22). Moreover, mtDNA facilitated mutations lead to premature aging  
22 in mice (23) and humans (24). Transgenic studies show that reducing whole-body or tissue  
23 specific mitochondrial superoxide dismutase (MnSOD), the enzyme that catalyses the  
24 dismutation of mitochondria-generated  $O_2^-$  to  $H_2O_2$  (25), increases evidence of oxidative  
25 damage and premature aging (26-28). Alternatively, overexpression of endogenous  
26 mitochondrial catalase lessens oxidant damage, reduces an overall burden of disease (29), and  
27 increases lifespan (30). Indications of impaired mitochondrial function extending beyond  
28 measures of oxidant production or damage are lacking. Whether there are age-induced  
29 alterations in actual electron transport function remains unanswered (4).

1 Reports of functional impairments to mitochondria with aging are seemingly paradoxical.  
2 Mitochondrial enzymatic expression, protein synthesis, volume density, and oxidative  
3 capacity have been reported to decrease with age in humans and animals quadricep skeletal  
4 muscle (19, 31-37) as well as in a collection of lower limb skeletal muscle representative of  
5 mixed glycolytic and oxidative fibers (38-40). The age-induced loss of mitochondrial protein  
6 expression and oxidative capacity, however, fails to decrease in skeletal muscle primarily  
7 composed of type two fast twitch glycolytic fibers (41-43). Modifications of mitochondrial  
8 content also differ with aging between *m. vastus lateralis* and *m. gastrocnemius* in humans  
9 (44). These differences have led to speculation that mitochondrial impairment with aging may  
10 differ across different skeletal muscle types (19, 45). *In vivo* metabolic imaging techniques  
11 have provided preliminary evidence to support this assumption with skeletal muscle primarily  
12 composed of fast-twitch fibers exhibiting the greatest age-induced impairments (46, 47).

13  
14 Accordingly the aim of this study is to examine mitochondrial protein expression along with  
15 analysis of respiratory capacity and control via high-resolution respirometry. Respirometric  
16 analysis using isolated mitochondrial preparations have been reported to exaggerate age  
17 induced changes in mitochondrial function (48). Mitochondrial isolation techniques disturb  
18 native mitochondrial reticular networks in skeletal muscle (49) producing atypical and  
19 individual organelles through unregulated means (50-52). This alters innate mitochondrial  
20 characteristics (48, 53-60) such as the loss of mitochondrial membrane integrity (61, 62) and  
21 the ability to oxidize fatty acids (56). For respirometric analysis we use saponin  
22 permeabilized skeletal muscle preparations. This preparation allows for direct access to  
23 skeletal muscle mitochondria while maintaining both the cytoplasmic ultrastructure (51, 63-  
24 68) and subcellular interactions with mitochondria (51, 53, 64, 67-69). Cellular bioenergetics  
25 and metabolic channeling are predicated upon these factors (63, 64, 67, 70). We have  
26 previously demonstrated that respirometric analysis using this *in situ* preparation in  
27 conjunction with biochemical assessment of mitochondria is more appropriate when  
28 attempting to differentiate between isolated changes in enzymatic expression versus an

1 alteration in the functional capacity of a subcellular system (71-74). Accordingly, this specific  
2 mitochondrial preparation serves as the best model to examine respiratory capacity and  
3 control with aging. Respirometric analyses were carried out on soleus (SOL), quadricep  
4 (QUAD), and lateral gastrocnemius (GAST) skeletal muscles, which represent type 1 slow  
5 twitch oxidative (SOL) and type 2 fast twitch glycolytic muscle (QUAD and GAST),  
6 respectively, in young (10-12 wk) and mature (74-76 wk) mice. Taking into account the  
7 inconsistent reports of mitochondrial impairment with age across different skeletal muscles,  
8 we hypothesize that alterations in mitochondrial function with age vary across skeletal muscle  
9 types, explaining the seemingly inconsistent past findings on this topic.

## 1 Experimental Procedures

### 2 *Ethical approval*

3 The experimental protocols using laboratory animals were approved by the Kantonales  
4 Veterinäramt Zürich (217/2010) and were performed in accordance with the Swiss animal  
5 protection laws and institutional guidelines.

### 7 *Experimental animals*

8 A total of 24 male C57Bl/6 mice were used in the completion of this study, 12 young (10-12  
9 week old) and 12 mature (74-76 week old). All mice were housed in standard rodent cages  
10 (T3) with fixed temperature ( $21 \pm 1^\circ\text{C}$ ), free access to food and water, and a 12-h light-dark  
11 cycle. Animals were euthanized by means of carbon dioxide followed by rapid excision of  
12 SOL, QUAD, and GAST. These muscles represent a type 1 slow twitch oxidative muscle  
13 (SOL), and a type 2 fast twitch glycolytic muscle (QUAD and GAST), respectively. The  
14 skeletal muscles from one leg were quickly excised and placed in ice-cold biopsy solution for  
15 immediate respirometric analyses. The corresponding skeletal muscle from the opposite  
16 hindlimb were then removed, frozen in liquid nitrogen, and stored at  $-80^\circ\text{C}$  until processed for  
17 protein expression analysis (see *Muscle lysate preparation* and *SDS-PAGE and Western*  
18 *blotting*).

### 20 *Muscle lysate preparation*

21 The muscle samples were homogenized (Qiagen Tissuelyser II, Retsch, Haan, Germany) in a  
22 fresh batch of buffer containing the following (in mM): 10% glycerol, 20 sodium-  
23 pyrophosphate, 150 NaCl, 50 HEPES (pH 7.5), 1% NP-40, 20  $\beta$ -glycerophosphate, 2  
24  $\text{Na}_3\text{VO}_4$ , 10 NaF, 2 PMSF, 1 EDTA (pH 8.0), 1 EGTA (pH 8.0), 10  $\mu\text{g/ml}$  aprotinin, 10  
25  $\mu\text{g/ml}$  leupeptin, and 3 benzamidine. Afterwards samples were rotated end over end for 1 h at  
26  $4^\circ\text{C}$  and centrifuged at 16,500 g for 30 min at  $4^\circ\text{C}$ , and the supernatant (lysate) was used for  
27 further analysis. Total protein concentration in each sample was determined by a bovine  
28 serum albumin standard kit (Pierce, Rockford, IL), and all samples were diluted to the same

1 protein concentration in ddH<sub>2</sub>O and a modified 6 x Laemmli buffer (7 ml 0.5 M Tris base (pH  
2 6.8), 3 ml glycerol, 0.93 g DTT, 1 g SDS, and 1.2 mg bromophenol blue).

3  
4  
5  
6  
7  
8  
9 *SDS-PAGE and Western blotting*

10 Methods have been previously described in detail (75-77). Equal amounts (10 µg) of total  
11 muscle lysate proteins, determined during optimization of the different antibodies, were  
12 loaded in each well. Samples were loaded together with protein markers (Precision Plus All  
13 Blue and Dual Color, Bio-Rad Laboratories) on precasted gels (Bio-Rad Laboratories).  
14 Proteins were separated by SDS page gel electrophoresis and semidry transferred to a  
15 polyvinylidene fluoride membrane (Millipore). The membranes were blocked in either 2%  
16 skimmed milk or 3% BSA in Tris-buffered saline, including 0.1% Tween 20 (TBST) before  
17 an overnight incubation in primary antibody at 4°C. Thereafter, membranes were washed in  
18 TBST and incubated for 1 h at room temperature in horseradish peroxidase-conjugated  
19 secondary antibody. Membranes were then washed 3 x 15 min in TBST before the bands  
20 were visualized with ECL (Millipore) and recorded with a digital camera (ChemiDoc MP  
21 Imaging System, Bio-Rad). Quantification of the western blot band intensity was done using  
22 the Image Lab software programme (Bio-Rad) and determined as the total band intensity  
23 minus the background intensity. Primary antibodies were optimized by use of mouse muscle  
24 lysates to secure that the protein amount loaded would result in band signal intensities  
25 localized on the steep and linearly part of a standard curve. To determine changes in total  
26 protein expression, the following antibodies were used with the localization of the quantified  
27 signal noted: 3-hydroxyacyl coenzyme a dehydrogenase (HAD): 83 kDa, polyclonal ab54477  
28 (Abcam, UK); Mitochondrial Complex IV subunit 4, COXIV, (CIV): 16 kDa, monoclonal sc-  
58348 (Santa Cruz Biotechnology, USA) and Mitochondrial Complex I subunit NDUFB8  
(CI): 20 kDa (monoclonal ab110242), Mitochondrial Complex II, Succinate Dehydrogenase  
complex subunit B (CII): 30 kDa (monoclonal ab14714), Mitochondrial Complex III subunit  
Core 2 (CIII): 45 kDa (monoclonal ab14745), Mitochondrial Complex V ATP Synthase  
subunit alpha (CV): 55 kDa (monoclonal ab14748) all four included in the MitoProfile®

1 Total OXPHOS Human WB Antibody Cocktail (ab110411, Abcam, UK). The secondary  
2 antibodies used were horseradish peroxidase-conjugated goat anti-mouse and goat anti-rabbit  
3 (P-0447 and P-0448, DAKO, Denmark). All samples from the same muscle type were loaded  
4 on the same gel with young and mature muscles mixed. Signal intensity from each muscle  
5 sample was normalized to the mean signal intensity of the human standard.

#### 6 7 *Skeletal muscle preparation*

8 Each part was immediately placed in ice-cold biopsy preservation solution (BIOPS)  
9 containing 2.77 mM CaK<sub>2</sub>EGTA buffer, 7.23 mM K<sub>2</sub>EGTA buffer, 0.1 μM free calcium, 20  
10 mM imidazole, 20 mM taurine, 50 mM 2-(N-Morpholino)ethanesulfonic acid hydrate (K-  
11 MES), 0.5 mM dithiothreitol (DTT), 6.56 mM MgCl<sub>2</sub>•6H<sub>2</sub>O, 5.77 mM ATP, and 15 mM  
12 phosphocreatine (pH 7.1). Muscle samples were then gently dissected with a pair of fine  
13 tipped forceps achieving a high degree of fibre separation verified microscopically. Chemical  
14 permeabilization followed via incubation in 2 ml of BIOPS with saponin (50 μg/ml) for 30  
15 minutes in 4°C (Kuznetsov et al., 2004). Lastly, samples were washed with a mitochondrial  
16 respiration medium (MiR05) containing 0.5 mM EGTA, 3 mM MgCl<sub>2</sub>•6H<sub>2</sub>O, 60 mM K-  
17 lactobionate, 20 mM taurine, 10 mM KH<sub>2</sub>PO<sub>4</sub>, 20 mM HEPES, 110 mM sucrose, and 1 g/l  
18 bovine serum albumin (pH 7.1) for 10 minutes at 4°C.

#### 19 20 *Mitochondrial respiration measurements*

21 Muscle bundles were blotted dry and measured for wet weight in a balance-controlled scale  
22 (XS205 DualRange Analytical Balance, Mettler-Toledo AG, Switzerland) maintaining  
23 constant relative humidity, providing hydration consistency as well as stability of weight  
24 measurements. Respiration measurements were performed in mitochondrial respiration  
25 medium 06 (MiR06; MiR05 + catalase 280 IU/ml). Measurements of oxygen consumption  
26 were performed at 37°C using the high-resolution Oxygraph-2k (Oroboros, Innsbruck,  
27 Austria) with all additions in each substrate, uncoupler, and inhibitor titration protocol added  
28 in series. Standardized instrumental were performed to correct for back-diffusion of oxygen

1 into the chamber from the various components, leak from the exterior, oxygen consumption  
2 by the chemical medium, and sensor oxygen consumption. Oxygen flux was resolved by  
3 software allowing nonlinear changes in the negative time derivative of the oxygen  
4 concentration signal (Oxygraph 2k, Oroboros, Innsbruck, Austria). All experiments were  
5 carried out in a hyperoxygenated environment to prevent any potential oxygen diffusion  
6 limitation.

7  
8 *Respiratory titration protocols*

9 Each titration protocol was specific to the examination of individual aspects of respiratory  
10 control through a sequence of coupling and substrate states induced via separate titrations,  
11 which were added in series as presented. The concentrations of substrates, uncouplers, and  
12 inhibitors used were based on prior experiments conducted for optimization of the titration  
13 protocols (71-73). A description of all three protocols is given in Table 1.

14  
15 *Titration protocol 1*

- 16 • Leak respiration in absence of adenylates ( $L_N$ ) was induced with the addition of  
17 malate (2 mM) and octanoyl carnitine (0.2 mM). The  $L_N$  state represents the resting  
18 oxygen consumption of an unaltered and intact electron transport system free of  
19 adenylates.
- 20 • Maximal electron flow through ETF and fatty acid oxidative capacity,  $P_{ETF}$ , were both  
21 determined following the addition of ADP (5 mM). In the  $P_{ETF}$  state, the ETF linked  
22 transfer of electrons requires the metabolism of acetyl-CoA, hence the addition of  
23 malate, in order to facilitate convergent electron flow into the Q-junction from both  
24 CI and ETF allowing  $\beta$ -oxidation to proceed. The contribution of electron flow  
25 through CI is far below capacity and so here the rate limiting metabolic branch is  
26 electron transport through ETF such that malate + octanoyl carnitine + ADP  
27 stimulated respiration is representative of, rather than specific to, electron capacity  
28 through ETF (71, 78, 79).

- 1           • Submaximal state 3 respiratory capacity specific to CI,  $P_{CI}$ , was induced following the  
2           additions of glutamate (10 mM).
- 3           • Maximal state 3 respiration, oxidative phosphorylation capacity,  $P$ , was then induced  
4           with the addition of succinate (10 mM).  $P$  demonstrates a naturally intact electron  
5           transport system's capacity to catalyze a sequential set of redox reactions that are  
6           partially coupled to the production of ATP via ATP Synthase.  $P$  maintains an  
7           electrochemical gradient across the inner mitochondrial membrane dictated by the  
8           degree of coupling to the phosphorylation system (Gnaiger, 2009; Pesta & Gnaiger,  
9           2011). This maximal state 3 state represents respiration that is resultant to saturating  
10          concentrations of ADP and substrate supply for both CI and succinate dehydrogenase,  
11          CII. Convergent electron input to CI and CII provides higher respiratory values  
12          compared to the isolated respiration of either CI (pyruvate/glutamate + malate or  
13          glutamate + malate) or CII (succinate + rotenone) (Rasmussen & Rasmussen, 2000;  
14          Gnaiger, 2009). Consequently  $P$  presents more physiological relevance to the study of  
15          mitochondrial function (Brand & Nicholls, 2011) and is necessary to establish  
16          confirmation of a complete and intact electron transport system.
- 17          • As an internal control for compromised integrity of the mitochondrial preparation, the  
18          mitochondrial outer membrane was assessed with the addition of cytochrome c (10  
19           $\mu$ M). If respiration significantly increased following titration of cytochrome c, then  
20          the measurement was removed and not included in statistical analysis. There was no  
21          indication of mitochondrial damage in the measurements included in the study as  
22          demonstrated by the average 3.5%, 2.9%, 7.5%, 5.3%, 6.3%, and 2.3% change in  
23          young and mature QUAD, SOL, and GAST respiration, respectively. All were either  
24          below or within the accepted 5-15% elevation in respiration following exogenous  
25          cytochrome c titration, successfully verifying the integrity of the outer mitochondrial  
26          membrane (64).

- 1       • Phosphorylative restraint of electron transport was assessed by uncoupling ATP  
2       Synthase, CV from the electron transport system with the titration of the proton  
3       ionophore, carbonyl cyanide p-(trifluoromethoxy) phenylhydrazone (FCCP; 0.5  $\mu$ M  
4       per addition up to optimum concentrations ranging from 1.5–3  $\mu$ M) reaching electron  
5       transport system, ETS, capacity. The inner mitochondrial membrane potential is  
6       completely collapsed with an open transmembrane proton circuit in the ETS  
7       respiratory state. The uninhibited flow of electrons through the respiratory system can  
8       therefore indirectly serve as an indication of maximal mitochondrial membrane  
9       potential.
- 10      • Finally, rotenone (0.5  $\mu$ M) and antimycin A (2.5  $\mu$ M) were added, in sequence, to  
11      terminate respiration by inhibiting CI and CIII, respectively. With CI inhibited,  
12      electron flow is specific to CII, providing submaximal state 3 respiration through CII  
13      ( $P_{CII}$ ).
- 14      • Inhibition of respiration with antimycin a then allows for the determination and  
15      correction of residual oxygen consumption (ROX), indicative of non-mitochondrial  
16      oxygen consumption in the chamber.

18      *Titration protocol 2*

19      This titration protocol was necessary for determination of coupling control of electrons  
20      through CI.

- 21      •  $L_N$  - malate (2 mM) and pyruvate (5 mM)
- 22      •  $P_{CI}$  - ADP (5 mM)
- 23      • Internal control for mitochondrial outer membrane integrity - cytochrome c (10  $\mu$ M);  
24      There was no indication of mitochondrial damage in the measurements included in  
25      the study as demonstrated by the 0.3%, 1.3%, 0.1%, -0.3%, 4.3%, and -0.1% change  
26      in mouse young and mature QUAD, SOL, and GAST respiration, respectively.

- 1 • ETS - FCCP; 0.5  $\mu$ M per addition up to optimum concentrations ranging from 1.5–3
- 2  $\mu$ M)
- 3 • CI inhibition - rotenone (0.5  $\mu$ M)
- 4 • ROX - antimycin A (2.5  $\mu$ M)

### 6 *Titration protocol 3*

7 This titration protocol was necessary for determination of coupling control of electrons  
8 through CII.

- 9 • CI inhibition - rotenone (0.5  $\mu$ M)
- 10 •  $L_N$  - succinate (10 mM)
- 11 •  $P_{CII}$  - ADP (5 mM)
- 12 • Internal control for mitochondrial outer membrane integrity - cytochrome c (10  $\mu$ M);
- 13 There was no indication of mitochondrial damage in the measurements included in
- 14 the study as demonstrated by the 7.3%, 2.6%, 9.8%, 13.4%, 5.1%, and 7.3% change
- 15 in mouse young and mature QUAD, SOL, and GAST respiration, respectively.
- 16 • ETS - FCCP; 0.5  $\mu$ M per addition up to optimum concentrations ranging from 1.5–3
- 17  $\mu$ M)
- 18 • ROX - antimycin A (2.5  $\mu$ M)

19  
20 Respiriometric values representing  $P_{CI}$  and  $P_{CII}$  did not differ across titration protocols.  
21 Consequently all  $P_{CI}$  and  $P_{CII}$  values achieved with the titration protocols for 2 and 3,  
22 respectively, were grouped with complementing respiratory state from titration protocol 1.

### 25 *Data analysis*

26 All mass-specific respirometric values were controlled to account for the differences in  
27 mitochondrial content, as indicated by CII protein expression, across age and fiber types. In

1     doing so all CII protein expression data was adjusted to a value of 1. The degree by which the  
2     protein expression had to be adjusted to equal 1 was then applied to all mass-specific  
3     respirometric values corresponding with the appropriate age and skeletal muscle type,  
4     respectively. Values of  $P_{CI}$  controlling for CI protein expression,  $P_{ETF}$  controlling for HAD  
5     protein expression, and  $P$  controlling for CIII protein expression all were also adjusted using  
6     the same method.

8     For all statistical evaluations, a p-value of  $< 0.05$  was considered significant. Differences in  
9     respiratory capacities and protein expression with age and across skeletal muscle groups were  
10    initially compared using a two-way ANOVA. When an ANOVA was significant, differences  
11    in respiratory capacities and protein expression with age and across skeletal muscle groups  
12    were evaluated using pairwise comparisons with a Bonferroni adjustment (SPSS Statistics  
13    17.0, SPSS, Inc. Chicago, IL, USA). Indices of mitochondrial efficiency did not express a  
14    Gaussian distribution and therefore a Kruskal-Wallis ANOVA and the U-Mann Whitney tests  
15    were used to reveal differences between between younger and older muscle as well as  
16    comparisons across muscle groups within the respective age groups.

## Results

### *Skeletal muscle protein expression*

As shown in Fig. 1, protein expression for all mitochondrial enzymes was greatest in the slow-twitch SOL muscle. In young animals only the expression of CII and CIV differed between QUAD and GAST, both of which were lost with age. Only SOL expressed a change in mitochondrial protein content with age as CI, CII, and CV all increased (Fig 1A, 1B, and 1E, respectively). Though no significant changes in protein expression of CIII (Fig. 1C) or mitochondrial complex IV (CIV; Fig. 1D) were apparent, both complexes showed a tendency to diminish with age in GAST ( $p = 0.060$  and  $0.063$ , respectively). Collectively this analysis illustrates that the protein content for enzymes involved in mitochondrial oxidative phosphorylation is largely unaffected in primarily fast-twitch glycolytic muscle (QUAD and GAST) but slightly increased in primarily slow-twitch oxidative muscle (SOL) with age.

### *Mitochondrial respiration*

Main effects of age on mass-specific respiration ( $\text{pmol O}_2 \text{ min}^{-1} \text{ mg ww}^{-1}$ ) were observed for  $P_{\text{ETF}}$  ( $p = 0.011$ ) and  $P_{\text{CII}}$  ( $p = 0.008$ ). This was reflected by the higher  $P_{\text{ETF}}$  and  $P_{\text{CII}}$  in mature QUAD ( $p = 0.031$  and  $0.037$ , respectively; Figure 2E) and GAST ( $p = 0.011$  and  $0.016$ , respectively; Figure 2I) versus their younger counterparts. There was also a main effect of muscle type on mass-specific respiration as SOL has greater respiration across all states compared to both QUAD and GAST ( $p < 0.001$ ).

Mass-specific respiration does not take into account differences in mitochondrial content between samples (Fig 1). Accordingly, all respirometric analyses were adjusted for CII protein content, a biomarker shown to express the best concordance with mitochondrial

1 content and total cristae area as measured by transmission electron microscopy as well as  
2 myocellular respiratory capacity over protein concentrations for all other mitochondrial  
3 complexes (80). When controlling respiration to mitochondrial content the main effect of age  
4 on respiration capacity ( $\text{pmol O}_2 \text{ min}^{-1} \text{ CI}^{-1}$ ) appeared to be silenced by the divergent  
5 fluctuations in mitochondrial function across skeletal muscle types in response to age.  
6 Respiratory states representing  $P_{\text{CI}}$ ,  $P$ , and ETS in QUAD and  $P_{\text{CI}}$ ,  $P$ , ETS, and  $P_{\text{CII}}$  in SOL all  
7 lost respiratory capacity in response to age (Figures 2F and 2H). Conversely, GAST increased  
8 respiratory capacity at every respiratory state measured (Figure 2J) in response to age. The  
9 differences in respiratory capacity when controlling for mitochondrial content across skeletal  
10 muscle in younger and older mice is shown on Fig. 2B and 2D, respectively.

11  
12 *Respiratory capacity and coupling control specific to mitochondrial complexes I & III*

13 Electron transport and control specifically through CI and CIII are of particular interest as  
14 ROS production at each respective complex accounts for the majority of mitochondria-  
15 specific oxidant production (9-14). In order to isolate analysis to these specific complexes, all  
16  $P_{\text{CI}}$  values, including respirometric values from both titration protocols 1 and 2, and maximal  
17 state 3 respirometric values,  $P$ , were adjusted to account for the differences in CI and CII  
18 protein expression, respectively, with age and across muscle groups (Fig. 1B & D).

19  
20 There were main effects of age ( $p = 0.001$ ) on  $P_{\text{CI}}$  respiration when controlling for CI  
21 expression ( $\text{pmol O}_2 \text{ min}^{-1} \text{ CI}^{-1}$ ), which increased with age in both QUAD and GAST ( $p <$   
22  $0.001$ ) and decreased in SOL ( $p = 0.003$ ; Figures 3A-C). The coupling efficiency during  $P_{\text{CI}}$   
23 respiration deteriorated with age in GAST ( $p = 0.043$ ) and showed a tendency to diminish in  
24 QUAD as well ( $p = 0.085$ ; Table 2). Though no differences in respiratory capacity were  
25 observed across all young muscle groups during  $P_{\text{CI}}$  when controlling for CI, the coupling  
26 control was superior in young QUAD and GAST over SOL ( $p = 0.021$  and  $0.009$ ,  
27 respectively). In the older muscle both QUAD and GAST presented with higher  $P_{\text{CI}}$  than SOL

( $p < 0.001$ ) and both, again, expressed a tighter coupling efficiency than SOL ( $p = 0.004$  and  $p < 0.001$ ).

There were also main effects of age ( $p = 0.009$ ) on maximal state 3 respiration and oxidative phosphorylation capacity,  $P$ , when controlling for CIII protein expression ( $\text{pmol O}_2 \text{ min}^{-1} \text{ CIII}^{-1}$ ). Respiration capacity in both QUAD and GAST increased with age ( $p = 0.009$  and  $0.001$ , respectively) while SOL did not change ( $p = 0.144$ ). Differences across young muscle groups were evident between both QUAD and SOL versus GAST ( $p = 0.023$  and  $0.001$ , respectively) and across mature muscle groups with QUAD greater than SOL ( $p = 0.020$ ).

#### *Respiratory capacity and control specific to $\beta$ -oxidation*

Only values of fatty acid oxidative capacity,  $P_{\text{ETF}}$ , were adjusted to account for the differences in HAD protein expression (Figure 1D).  $P_{\text{ETF}}$  ( $\text{pmol O}_2 \text{ min}^{-1} \text{ HAD}^{-1}$ ) increased with age in QUAD ( $p = 0.004$ ) and showed a tendency to increase in GAST ( $p = 0.065$ ). Differences across young and mature muscle groups were evident with both QUAD and GAST far below SOL ( $p < 0.001$ ). Though  $P_{\text{ETF}}$ , when controlling for HAD, did not change in SOL, the coupling efficiency during  $\beta$ -oxidation diminished with age. Despite this decrease with age, the coupling control of electron transport during  $\beta$ -oxidation in SOL was significantly better in younger and older QUAD ( $p = 0.01$  and  $0.05$ , respectively). Coupling control during fat oxidation did not change with age in QUAD or GAST, though it did differ between young SOL and GAST ( $p = 0.05$ ). This difference was lost with age (Table 2).

**Discussion**

The aim of this study was to analyze the effect of biological aging on respiratory capacities and mitochondrial coupling control across different skeletal muscle types as a function of age. Our main findings are: 1.) Mitochondrial function is dependent on skeletal muscle type, irrespective of age; 2.) Submaximal state 3 respiration specific to mitochondrial complex I,  $P_{CI}$ , increased in both QUAD and GAST but decreased in SOL when controlling for complex I protein expression; 3.) Coupling control during  $P_{CI}$  was also lost with age in GAST and indicated a tendency for deterioration in QUAD but remained unchanged in SOL; 4.) Maximal state 3 respiration and oxidative phosphorylation capacity,  $P$ , increased with age in QUAD and GAST but not SOL when controlling for mitochondrial complex III protein expression; and finally 5.) While the capacity for fat respiration increased with age in QUAD when controlling for differences in 3-hydroxyacyl coenzyme a dehydrogenase (HAD) protein expression across skeletal muscle types, the coupling control during fat oxidation worsened with age only in SOL.

*Variations in mitochondrial function across fiber types*

There is some dispute on whether or not differences in respiratory capacity fluctuate across different skeletal muscle types that vary in their biochemical make-up, tailoring oxidative function to specific metabolic demand (81). Initial reports suggested that respiratory differences could be accounted for simply by the differences in mitochondrial content (50, 82). This has since been refuted as various skeletal muscles have been shown to express respiratory differences across muscle types (46, 47, 83, 84). We recently substantiated these differences in mitochondrial function across muscle types as respiration capacities in both

1 GAST and QUAD were greater than those in SOL at  $P_{CL}$ ,  $P_{CII}$ ,  $P$ , and ETS respiratory states  
2 when normalizing mass-specific respiration to citrate synthase activity (85). While it seems  
3 evident that differences in function exist across different skeletal muscle fiber types, even  
4 when controlling for the disproportionate expression of mitochondria, the data presented here  
5 demonstrate how important normalization of the mass-specific respirometric values can be to  
6 overall data interpretation.

7  
8 Our findings specific to mitochondrial protein expression are contrary to studies suggestive of  
9 a progressive loss of mitochondria with age (34, 48). We cannot exclude the possibility that  
10 some mitochondrial protein/fragments may have been lost as a result of our homogenization  
11 and centrifugation procedures. Thus we cannot confirm that our mitochondrial protein  
12 determination is representative of the total per volume of muscle mass, possibly explaining  
13 the differences between studies. Alternatively, however, our results are in accordance with  
14 several studies reporting negligible to minor changes in mitochondrial protein expression with  
15 age, including an increase of expression dependent on skeletal muscle type (32, 33, 45, 86).  
16 There is also evidence in mice of *increased* skeletal muscle mitochondrial protein synthesis  
17 with advancing age (86). Although it is unlikely that the preferential loss of mitochondrial  
18 protein during homogenization and centrifugation procedures biased our results, we cannot  
19 definitively exclude this possibility.

#### 20 21 *Skeletal muscle mitochondrial respiratory capacity and control across skeletal muscle types* 22 *with age*

23 Mitochondrial respiratory capacities across several different states diminished with age in  
24 QUAD and SOL (Fig. 2F & H). These results coincide with previous reports where oxidative  
25 capacity is reported to decline with age in either quadriceps or mixed muscle homogenates (19,  
26 31, 33, 35, 36, 38, 39). Alternatively, mitochondrial respiratory capacities across all states  
27 increased with age in GAST (Figure 2J). The increase in respiratory capacity with age in  
28 GAST also corresponds with previous work that demonstrated a greater reliance with age of

1 oxidative phosphorylation for ATP synthesis in primarily type 2 fast twitch glycolytic skeletal  
2 muscle (41, 42, 87).  
3  
4 Mitochondria serve as a primary source of *in vivo* oxidant production (2-5) with the primary  
5 oxidant production occurring at CI (6-8) and CIII (9-14). Despite the macro decreases in  
6 mitochondrial specific respiratory capacity in QUAD (Fig. 2F), respiration and electron flow  
7 specifically through CI and CIII increased (Fig. 3A & 4A). Coupling control during  $P_{CI}$  also  
8 had a tendency to deteriorate in QUAD ( $p = 0.085$ ) in response to age (Table 2). Respiration  
9 and electron flow specifically through CI and CIII also increased in GAST, while coupling  
10 control during  $P_{CI}$  worsened with age (Table 2). Electron coupling control is indicative of  
11 oxidant production as mitochondrial production of superoxide is closely related to  
12 mitochondrial coupling efficiency during respiration (9). Moreover, increased mitochondrial  
13 respiration capacity also results in increased oxidative damage and shorter lifespan (27).  
14 Respiratory capacity through CI diminished while capacity through CIII and electron  
15 coupling control through CI remained unaffected by age in the slow twitch oxidative SOL  
16 (Fig 3B, 4B, and Table 2, respectively). Highly glycolytic skeletal muscle has been shown to  
17 have higher oxidant production with a reciprocal lower capacity for oxidant scavenging  
18 compared to highly oxidative muscle (88). Predominantly fast twitch skeletal muscle also  
19 have been reported to accrue age-associated oxidative damage, as assessed with protein  
20 carbonyl profiles across different skeletal muscle types, more rapidly than slow twitch  
21 oxidative muscle (89). Collectively the results from this study, in corroboration with these  
22 previous findings, provide the direct evidence of a predisposition to electron transport system  
23 dysfunction with age in type 2 fast twitch glycolytic skeletal muscle that is not observed in  
24 type 1 slow twitch oxidative muscle and has been previously suggested in humans using  
25 indirect metabolic imaging techniques (46, 47). Preliminary evidence suggests that caloric  
26 restriction (90) and exercise (91) reduce mitochondrial oxidant production and may serve to  
27 counterbalance these age-related impairments in electron transport.  
28

1 Ratios of coupling control are based on the supposition that a tightly coupled system can be  
2 distinguished from a dyscoupled system by the magnitude of difference between two steady  
3 respiratory states with identical substrate supply (92). We used leak control ratios as our  
4 indices of mitochondrial coupling control efficiency (Table 2). Leak control ratios are  
5 produced between two reciprocal respiratory states; a low flux state (i.e.  $L_N$  with malate and  
6 pyruvate, state 4 respiration) compared to an equivalent high respiratory flux state (i.e.  $P_{CI}$ ,  
7 submaximal state 3 respiration). An identical substrate supply is necessary to pair  
8 corresponding states. Flux control ratios demonstrate coupling efficiency using a theoretical  
9 minimum of 0.0, which indicates a fully coupled system, to a value of 1.0 representing a fully  
10 non-coupled or dyscoupled system (63). While we show evidence of a loss of coupling  
11 control with aging during  $P_{CI}$  in GAST and a tendency in QUAD, unfortunately coupling  
12 efficiency during maximal state 3 respiration could not be determined with the titration  
13 protocols utilized as there was no reciprocal leak state measured for P.

#### 14 *Respiratory capacity and control of fat oxidation with aging*

15 We found that the capacity for fat respiration increased with age without a reciprocal loss of  
16 coupling efficiency during  $\beta$ -oxidation in QUAD when controlling for differences in HAD  
17 protein expression. Conversely, capacity for fat respiration was unaltered with age in SOL,  
18 though the coupling control during fat oxidation diminished. Neither respiratory capacity nor  
19 control of fat oxidation was altered in GAST. Skeletal muscle intramyocellular lipid (IMCL)  
20 stores increase in parallel with age-related decreases in mitochondria (37). Moreover, IMCL  
21 content is also reported to drift away from the mitochondrial reticulum with age (37). The  
22 dysregulation of fat metabolism within skeletal muscle is associated with the development of  
23 insulin resistance and metabolic disease (93-95). The loss of mitochondrial coupling  
24 efficiency in type I slow twitch fibers, such as observed here, may in part explain the reported  
25 insulin resistance in healthy, lean, elderly subjects (38). This is of interest in regards to  
26 metabolic disease as well as aging and merits further investigation.

1     *Conclusion*

2     Here we directly demonstrate impairments of mitochondrial function in response to aging in  
3     skeletal muscle. The specific age-induced alteration in function is dependent on skeletal  
4     muscle type. Skeletal muscle composed primarily of type 2 fast twitch glycolytic fibers are  
5     predisposed to progressive impairments in mitochondrial function with age as type I slow  
6     twitch oxidative fibers appear to protect against this effect.

**Table 2. Mitochondrial coupling efficiency with age**

	Young QUAD	Mature QUAD	Young SOL	Mature SOL	Young GAST	Mature GAST
<b>LCR<sub>ETF</sub></b>	0.54±0.16 <sup>†</sup>	0.53±0.18 <sup>†</sup>	0.33±0.09 <sup>*†‡</sup>	0.41±0.05 <sup>*†</sup>	0.57±0.29 <sup>‡</sup>	0.52±0.10
<b>LCR<sub>CI</sub></b>	0.15±0.03 <sup>†§</sup>	0.20±0.07 <sup>†§</sup>	0.24±0.11 <sup>†‡</sup>	0.29±0.06 <sup>†‡</sup>	0.12±0.06 <sup>*‡</sup>	0.17±0.03 <sup>*‡</sup>
<b>LCR<sub>CII</sub></b>	0.69±0.13	0.76±0.07	0.54±0.25	0.72±0.11	0.68±0.19	0.66±0.11

**Table 2. Mitochondrial coupling efficiency with age.** Leak control ratios (LCR) as indices of mitochondrial coupling and respiratory control across different skeletal muscles with age. LCR<sub>ETF</sub>, coupling efficiency of electron transfer through electron transferring flavoprotein (ETF) during  $\beta$ -oxidation; P<sub>CI</sub>, coupling efficiency of electron transfer during respiration through mitochondrial complex I (CI); and P<sub>CII</sub>, coupling efficiency of electron transfer during respiration through mitochondrial complex II (CII). QUAD, quadriceps; SOL, soleus; and GAST, gastrocnemius. \*, †, and ‡, indicate an effect of age, difference between QUAD vs. SOL; and difference in SOL vs. GAST, respectively with  $p < 0.05$ . § is a difference with age,  $p = 0.085$ . Data are presented as mean  $\pm$  SD.

**FIGURE LEGENDS**

**Figure 1. Protein expression of mitochondrial complexes and proteins with age.**

Skeletal muscle protein expression determined in young (10-12 wks) and mature (74-76 wks) C57Bl/6 mice. Protein expression for (A) CI, mitochondrial complex I or NADH dehydrogenase; (B) CII, mitochondrial complex II or succinate dehydrogenase; (C) CIII, mitochondrial complex III or cytochrome *bc<sub>1</sub>* complex; (D) CIV, mitochondrial complex IV or cytochrome c oxidase; (E) CV, mitochondrial complex V or ATP Synthase; and (F) HAD, 3-hydroxyacyl coenzyme a dehydrogenase, is illustrated in response to age and across skeletal muscles. Example blots for one analysis from one animal are shown above the graph. Values are means  $\pm$  SD. a indicates significant difference in age within a skeletal muscle,  $p < 0.05$ ; b shows significant difference between soleus (black) from both quadricep (grey) and lateral gastrocnemius (white) within the same age,  $p < 0.05$ ; and c indicates differences between quadricep and gastrocnemius within the same age,  $p < 0.05$ .

**Figure 2. Skeletal muscle respirometric analysis.** Mass-specific respiration across muscle groups in (A) young and (C) mature animals. Mass-specific respiration with age in mouse (E) quadricep, (G) soleus, and (I) gastrocnemius skeletal muscles. Mitochondrial-specific respiration controlling for mitochondrial content, as assessed by mitochondrial complex II protein expression (80), across skeletal muscles in (B) young and (D) mature animals. Mitochondrial-specific respiration with age in mouse

(F) quadricep, (H) soleus, and (J) gastrocnemius skeletal muscles.  $L_N$ , leak respiration without adenylates;  $P_{EFT}$ , maximal fatty acid oxidation;  $P_{CI}$ , submaximal state 3 respiration through mitochondrial complex I (CI);  $P$ , maximal state 3 respiration – oxidative phosphorylation capacity; Cyt C, cytochrome c, internal test of mitochondrial membrane integrity; ETS, electron transport system capacity; and  $P_{CII}$ , submaximal state 3 respiration through mitochondrial complex II (CII). Data presented as mean  $\pm$  SD. \*, \*\*, \*\*\* indicates significant difference of  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq 0.001$ , respectively.

**Figure 3. Respiratory capacity and control through mitochondrial complex I (CI).** Submaximal state 3 respiratory capacity specific to CI ( $P_{CI}$ ) when controlling for CI protein expression with age in (A) quadricep, (B) soleus, and (C) gastrocnemius skeletal muscles. \*, \*\*, \*\*\* indicates significant difference of age,  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq 0.001$ , respectively.

**Figure 4. Respiratory capacity and control through mitochondrial complex III (CIII).** Maximal state 3 respiration and oxidative phosphorylation capacity ( $P$ ) when controlling for CIII protein expression with age in (A) quadricep, (B) soleus, and (C) gastrocnemius skeletal muscles. \*, \*\*, \*\*\* indicates significant difference of age,  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq 0.001$ , respectively.

**Figure 5. Respiratory capacity and control through electron transferring flavoprotein (ETF) during maximal fat respiration.** Submaximal state 3 respiratory capacity specific to the capacity for fat oxidation and electron transfer through ETF ( $P_{ETF}$ ) when controlling for 3-hydroxyacyl coenzyme a dehydrogenase (HAD) protein

1 expression with age in (A) quadricep, (B) soleus, and (C) gastrocnemius skeletal  
2 muscles. \*, \*\*, \*\*\* indicates significant difference of age,  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq$   
3 0.001, respectively. # indicates a tendency of a difference with age,  $p = 0.065$ .

**Short running page headline:** Skeletal muscle mitochondrial function with aging

## 1 Summary (145)

2 The etiology of mammalian senescence is suggested to involve the progressive impairment of  
3 mitochondrial function, however direct observations of age-induced alterations in actual  
4 respiratory chain function are lacking. Accordingly we assessed mitochondrial function via  
5 high-resolution respirometry and mitochondrial protein expression in soleus (SOL), quadricep  
6 (QUAD), and lateral gastrocnemius (GAST) skeletal muscles, which represent type 1 slow  
7 twitch oxidative (SOL), and type 2 fast twitch glycolytic muscle (QUAD and GAST),  
8 respectively, in young (10-12 wk) and mature (74-76 wk) mice. Electron transport through  
9 mitochondrial complexes I and III increase with age in QUAD and GAST, which is not  
10 observed in SOL. Mitochondrial coupling efficiency during respiration through complex I  
11 also deteriorates with age in GAST and shows a tendency ( $p = 0.085$ ) to worsen in QUAD.  
12 This data demonstrates actual alterations in electron transport function that occur with age and  
13 are dependent on skeletal muscle type.

1     **Introduction**

2     An inherent flaw of the bioenergetic reliance on aerobic metabolism to sustain life is the  
3     corollary oxidant production (1), and consequently mitochondria serve as the primary source  
4     of *in vivo* oxidant production (2-5). Mitochondrial-derived reactive oxygen species (ROS) are  
5     largely accounted for by superoxide ( $O_2^-$ ) production into the mitochondrial matrix at  
6     mitochondrial complex I (CI) (6-8) and into both the matrix and mitochondrial  
7     intermembrane space at mitochondrial complex III (CIII) (9-14). The progression of ROS  
8     production beyond hormetic concentrations precipitates deleterious and indiscriminate  
9     oxidation of nucleic acids, proteins, and lipids (5, 15, 16). These pernicious effects then  
10    correspondingly impair mitochondrial function, which result in greater oxidant production,  
11    and so on leading to a “vicious cycle” and eminent cellular demise (4, 15, 17). The  
12    mitochondrial theory of aging asserts that the biological aging process is facilitated by this  
13    progressive accrual of mitochondrial (mt) DNA damage and reciprocal decline of  
14    mitochondrial function (18). While evidence of increasing mtDNA alteration with age is  
15    supported by the literature, data suggestive of an impairment of mitochondrial function with  
16    aging are inconsistent.

17  
18    Senescence corresponds with mounting indications of nuclear and mtDNA damage in both  
19    humans and animals (19-22). Moreover, mtDNA facilitated mutations lead to premature aging  
20    in mice (23) and humans (24). Transgenic studies show that reducing whole-body or tissue  
21    specific mitochondrial superoxide dismutase (MnSOD), the enzyme that catalyses the  
22    dismutation of mitochondria-generated  $O_2^-$  to  $H_2O_2$  (25), increases evidence of oxidative  
23    damage and premature aging (26-28). Alternatively, overexpression of endogenous  
24    mitochondrial catalase lessens oxidant damage, reduces an overall burden of disease (29), and  
25    increases lifespan (30). Indications of impaired mitochondrial function extending beyond  
26    measures of oxidant production or damage are lacking. Whether there are age-induced  
27    alterations in actual electron transport function remains unanswered (4).

1 Reports of functional impairments to mitochondria with aging are seemingly paradoxical.  
2 Mitochondrial enzymatic expression, protein synthesis, volume density, and oxidative  
3 capacity have been reported to decrease with age in humans and animals quadricep skeletal  
4 muscle (19, 31-37) as well as in a collection of lower limb skeletal muscle representative of  
5 mixed glycolytic and oxidative fibers (38-40). The age-induced loss of mitochondrial protein  
6 expression and oxidative capacity, however, fails to decrease in skeletal muscle primarily  
7 composed of type two fast twitch glycolytic fibers (41-43). Modifications of mitochondrial  
8 content also differ with aging between *m. vastus lateralis* and *m. gastrocnemius* in humans  
9 (44). These differences have led to speculation that mitochondrial impairment with aging may  
10 differ across different skeletal muscle types (19, 45). *In vivo* metabolic imaging techniques  
11 have provided preliminary evidence to support this assumption with skeletal muscle primarily  
12 composed of fast-twitch fibers exhibiting the greatest age-induced impairments (46, 47).

13  
14 Accordingly the aim of this study is to examine mitochondrial protein expression along with  
15 analysis of respiratory capacity and control via high-resolution respirometry. Respirometric  
16 analysis using isolated mitochondrial preparations have been reported to exaggerate age  
17 induced changes in mitochondrial function (48). Mitochondrial isolation techniques disturb  
18 native mitochondrial reticular networks in skeletal muscle (49) producing atypical and  
19 individual organelles through unregulated means (50-52). This alters innate mitochondrial  
20 characteristics (48, 53-60) such as the loss of mitochondrial membrane integrity (61, 62) and  
21 the ability to oxidize fatty acids (56). For respirometric analysis we use saponin  
22 permeabilized skeletal muscle preparations. This preparation allows for direct access to  
23 skeletal muscle mitochondria while maintaining both the cytocellular ultrastructure (51, 63-  
24 68) and subcellular interactions with mitochondria (51, 53, 64, 67-69). Cellular bioenergetics  
25 and metabolic channeling are predicated upon these factors (63, 64, 67, 70). We have  
26 previously demonstrated that respirometric analysis using this *in situ* preparation in  
27 conjunction with biochemical assessment of mitochondria is more appropriate when  
28 attempting to differentiate between isolated changes in enzymatic expression versus an

1 alteration in the functional capacity of a subcellular system (71-74). Accordingly, this specific  
2 mitochondrial preparation serves as the best model to examine respiratory capacity and  
3 control with aging. Respirometric analyses were carried out on soleus (SOL), quadricep  
4 (QUAD), and lateral gastrocnemius (GAST) skeletal muscles, which represent type 1 slow  
5 twitch oxidative (SOL) and type 2 fast twitch glycolytic muscle (QUAD and GAST),  
6 respectively, in young (10-12 wk) and mature (74-76 wk) mice. Taking into account the  
7 inconsistent reports of mitochondrial impairment with age across different skeletal muscles,  
8 we hypothesize that alterations in mitochondrial function with age vary across skeletal muscle  
9 types, explaining the seemingly inconsistent past findings on this topic.

## 1 Experimental Procedures

### 2 *Ethical approval*

3 The experimental protocols using laboratory animals were approved by the Kantonales  
4 Veterinäramt Zürich (217/2010) and were performed in accordance with the Swiss animal  
5 protection laws and institutional guidelines.

### 7 *Experimental animals*

8 A total of 24 male C57Bl/6 mice were used in the completion of this study, 12 young (10-12  
9 week old) and 12 mature (74-76 week old). All mice were housed in standard rodent cages  
10 (T3) with fixed temperature ( $21\pm1^{\circ}\text{C}$ ), free access to food and water, and a 12-h light-dark  
11 cycle. Animals were euthanized by means of carbon dioxide followed by rapid excision of  
12 SOL, QUAD, and GAST. These muscles represent a type 1 slow twitch oxidative muscle  
13 (SOL), and a type 2 fast twitch glycolytic muscle (QUAD and GAST), respectively. The  
14 skeletal muscles from one leg were quickly excised and placed in ice-cold biopsy solution for  
15 immediate respirometric analyses. The corresponding skeletal muscle from the opposite  
16 hindlimb were then removed, frozen in liquid nitrogen, and stored at  $-80^{\circ}\text{C}$  until processed for  
17 protein expression analysis (see *Muscle lysate preparation* and *SDS-PAGE and Western*  
18 *blotting*).

### 20 *Muscle lysate preparation*

21 The muscle samples were homogenized (Qiagen Tissuelyser II, Retsch, Haan, Germany) in a  
22 fresh batch of buffer containing the following (in mM): 10% glycerol, 20 sodium-  
23 pyrophosphate, 150 NaCl, 50 HEPES (pH 7.5), 1% NP-40, 20  $\beta$ -glycerophosphate, 2  
24  $\text{Na}_3\text{VO}_4$ , 10 NaF, 2 PMSF, 1 EDTA (pH 8.0), 1 EGTA (pH 8.0), 10  $\mu\text{g/ml}$  aprotinin, 10  
25  $\mu\text{g/ml}$  leupeptin, and 3 benzamidine. Afterwards samples were rotated end over end for 1 h at  
26  $4^{\circ}\text{C}$  and centrifuged at 16,500 g for 30 min at  $4^{\circ}\text{C}$ , and the supernatant (lysate) was used for  
27 further analysis. Total protein concentration in each sample was determined by a bovine  
28 serum albumin standard kit (Pierce, Rockford, IL), and all samples were diluted to the same

1 protein concentration in ddH<sub>2</sub>O and a modified 6 x Laemmli buffer (7 ml 0.5 M Tris base (pH  
2 6.8), 3 ml glycerol, 0.93 g DTT, 1 g SDS, and 1.2 mg bromophenol blue).

3  
4  
5  
6  
7  
8  
9 *SDS-PAGE and Western blotting*

10 Methods have been previously described in detail (75-77). Equal amounts (10 µg) of total  
11 muscle lysate proteins, determined during optimization of the different antibodies, were  
12 loaded in each well. Samples were loaded together with protein markers (Precision Plus All  
13 Blue and Dual Color, Bio-Rad Laboratories) on precasted gels (Bio-Rad Laboratories).  
14 Proteins were separated by SDS page gel electrophoresis and semidry transferred to a  
15 polyvinylidene fluoride membrane (Millipore). The membranes were blocked in either 2%  
16 skimmed milk or 3% BSA in Tris-buffered saline, including 0.1% Tween 20 (TBST) before  
17 an overnight incubation in primary antibody at 4°C. Thereafter, membranes were washed in  
18 TBST and incubated for 1 h at room temperature in horseradish peroxidase-conjugated  
19 secondary antibody. Membranes were then washed 3 x 15 min in TBST before the bands  
20 were visualized with ECL (Millipore) and recorded with a digital camera (ChemiDoc MP  
21 Imaging System, Bio-Rad). Quantification of the western blot band intensity was done using  
22 the Image Lab software programme (Bio-Rad) and determined as the total band intensity  
23 minus the background intensity. Primary antibodies were optimized by use of mouse muscle  
24 lysates to secure that the protein amount loaded would result in band signal intensities  
25 localized on the steep and linearly part of a standard curve. To determine changes in total  
26 protein expression, the following antibodies were used with the localization of the quantified  
27 signal noted: 3-hydroxyacyl coenzyme a dehydrogenase (HAD): 83 kDa, polyclonal ab54477  
28 (Abcam, UK); Mitochondrial Complex IV subunit 4, COXIV, (CIV): 16 kDa, monoclonal sc-  
58348 (Santa Cruz Biotechnology, USA) and Mitochondrial Complex I subunit NDUFB8  
(CI): 20 kDa (monoclonal ab110242), Mitochondrial Complex II, Succinate Dehydrogenase  
complex subunit B (CII): 30 kDa (monoclonal ab14714), Mitochondrial Complex III subunit  
Core 2 (CIII): 45 kDa (monoclonal ab14745), Mitochondrial Complex V ATP Synthase  
subunit alpha (CV): 55 kDa (monoclonal ab14748) all four included in the MitoProfile®

1 Total OXPHOS Human WB Antibody Cocktail (ab110411, Abcam, UK). The secondary  
2 antibodies used were horseradish peroxidase-conjugated goat anti-mouse and goat anti-rabbit  
3 (P-0447 and P-0448, DAKO, Denmark). All samples from the same muscle type were loaded  
4 on the same gel with young and mature muscles mixed. Signal intensity from each muscle  
5 sample was normalized to the mean signal intensity of the human standard.

#### 6 7 *Skeletal muscle preparation*

8 Each part was immediately placed in ice-cold biopsy preservation solution (BIOPS)  
9 containing 2.77 mM CaK<sub>2</sub>EGTA buffer, 7.23 mM K<sub>2</sub>EGTA buffer, 0.1  $\mu$ M free calcium, 20  
10 mM imidazole, 20 mM taurine, 50 mM 2-(N-Morpholino)ethanesulfonic acid hydrate (K-  
11 MES), 0.5 mM dithiothreitol (DTT), 6.56 mM MgCl<sub>2</sub>•6H<sub>2</sub>O, 5.77 mM ATP, and 15 mM  
12 phosphocreatine (pH 7.1). Muscle samples were then gently dissected with a pair of fine  
13 tipped forceps achieving a high degree of fibre separation verified microscopically. Chemical  
14 permeabilization followed via incubation in 2 ml of BIOPS with saponin (50  $\mu$ g/ml) for 30  
15 minutes in 4°C (Kuznetsov et al., 2004). Lastly, samples were washed with a mitochondrial  
16 respiration medium (MiR05) containing 0.5 mM EGTA, 3 mM MgCl<sub>2</sub>•6H<sub>2</sub>O, 60 mM K-  
17 lactobionate, 20 mM taurine, 10 mM KH<sub>2</sub>PO<sub>4</sub>, 20 mM HEPES, 110 mM sucrose, and 1 g/l  
18 bovine serum albumin (pH 7.1) for 10 minutes at 4°C.

#### 19 20 *Mitochondrial respiration measurements*

21 Muscle bundles were blotted dry and measured for wet weight in a balance-controlled scale  
22 (XS205 DualRange Analytical Balance, Mettler-Toledo AG, Switzerland) maintaining  
23 constant relative humidity, providing hydration consistency as well as stability of weight  
24 measurements. Respiration measurements were performed in mitochondrial respiration  
25 medium 06 (MiR06; MiR05 + catalase 280 IU/ml). Measurements of oxygen consumption  
26 were performed at 37°C using the high-resolution Oxygraph-2k (Oroboros, Innsbruck,  
27 Austria) with all additions in each substrate, uncoupler, and inhibitor titration protocol added  
28 in series. Standardized instrumental were performed to correct for back-diffusion of oxygen

1 into the chamber from the various components, leak from the exterior, oxygen consumption  
2 by the chemical medium, and sensor oxygen consumption. Oxygen flux was resolved by  
3 software allowing nonlinear changes in the negative time derivative of the oxygen  
4 concentration signal (Oxygraph 2k, Oroboros, Innsbruck, Austria). All experiments were  
5 carried out in a hyperoxygenated environment to prevent any potential oxygen diffusion  
6 limitation.

7  
8 *Respiratory titration protocols*

9 Each titration protocol was specific to the examination of individual aspects of respiratory  
10 control through a sequence of coupling and substrate states induced via separate titrations,  
11 which were added in series as presented. The concentrations of substrates, uncouplers, and  
12 inhibitors used were based on prior experiments conducted for optimization of the titration  
13 protocols (71-73). A description of all three protocols is given in Table 1.

14  
15 *Titration protocol 1*

- 16 • Leak respiration in absence of adenylates ( $L_N$ ) was induced with the addition of  
17 malate (2 mM) and octanoyl carnitine (0.2 mM). The  $L_N$  state represents the resting  
18 oxygen consumption of an unaltered and intact electron transport system free of  
19 adenylates.
- 20 • Maximal electron flow through ETF and fatty acid oxidative capacity,  $P_{ETF}$ , were both  
21 determined following the addition of ADP (5 mM). In the  $P_{ETF}$  state, the ETF linked  
22 transfer of electrons requires the metabolism of acetyl-CoA, hence the addition of  
23 malate, in order to facilitate convergent electron flow into the Q-junction from both  
24 CI and ETF allowing  $\beta$ -oxidation to proceed. The contribution of electron flow  
25 through CI is far below capacity and so here the rate limiting metabolic branch is  
26 electron transport through ETF such that malate + octanoyl carnitine + ADP  
27 stimulated respiration is representative of, rather than specific to, electron capacity  
28 through ETF (71, 78, 79).

- 1       • Submaximal state 3 respiratory capacity specific to CI,  $P_{CI}$ , was induced following the  
2       additions of glutamate (10 mM).
- 3       • Maximal state 3 respiration, oxidative phosphorylation capacity,  $P$ , was then induced  
4       with the addition of succinate (10 mM).  $P$  demonstrates a naturally intact electron  
5       transport system's capacity to catalyze a sequential set of redox reactions that are  
6       partially coupled to the production of ATP via ATP Synthase.  $P$  maintains an  
7       electrochemical gradient across the inner mitochondrial membrane dictated by the  
8       degree of coupling to the phosphorylation system (Gnaiger, 2009; Pesta & Gnaiger,  
9       2011). This maximal state 3 state represents respiration that is resultant to saturating  
10      concentrations of ADP and substrate supply for both CI and succinate dehydrogenase,  
11      CII. Convergent electron input to CI and CII provides higher respiratory values  
12      compared to the isolated respiration of either CI (pyruvate/glutamate + malate or  
13      glutamate + malate) or CII (succinate + rotenone) (Rasmussen & Rasmussen, 2000;  
14      Gnaiger, 2009). Consequently  $P$  presents more physiological relevance to the study of  
15      mitochondrial function (Brand & Nicholls, 2011) and is necessary to establish  
16      confirmation of a complete and intact electron transport system.
- 17      • As an internal control for compromised integrity of the mitochondrial preparation, the  
18      mitochondrial outer membrane was assessed with the addition of cytochrome c (10  
19       $\mu$ M). If respiration significantly increased following titration of cytochrome c, then  
20      the measurement was removed and not included in statistical analysis. There was no  
21      indication of mitochondrial damage in the measurements included in the study as  
22      demonstrated by the average 3.5%, 2.9%, 7.5%, 5.3%, 6.3%, and 2.3% change in  
23      young and mature QUAD, SOL, and GAST respiration, respectively. All were either  
24      below or within the accepted 5-15% elevation in respiration following exogenous  
25      cytochrome c titration, successfully verifying the integrity of the outer mitochondrial  
26      membrane (64).

- 1       • Phosphorylative restraint of electron transport was assessed by uncoupling ATP  
2       Synthase, CV from the electron transport system with the titration of the proton  
3       ionophore, carbonyl cyanide p-(trifluoromethoxy) phenylhydrazone (FCCP; 0.5  $\mu$ M  
4       per addition up to optimum concentrations ranging from 1.5–3  $\mu$ M) reaching electron  
5       transport system, ETS, capacity. The inner mitochondrial membrane potential is  
6       completely collapsed with an open transmembrane proton circuit in the ETS  
7       respiratory state. The uninhibited flow of electrons through the respiratory system can  
8       therefore indirectly serve as an indication of maximal mitochondrial membrane  
9       potential.
- 10       • Finally, rotenone (0.5  $\mu$ M) and antimycin A (2.5  $\mu$ M) were added, in sequence, to  
11       terminate respiration by inhibiting CI and CIII, respectively. With CI inhibited,  
12       electron flow is specific to CII, providing submaximal state 3 respiration through CII  
13       ( $P_{CII}$ ).
- 14       • Inhibition of respiration with antimycin a then allows for the determination and  
15       correction of residual oxygen consumption (ROX), indicative of non-mitochondrial  
16       oxygen consumption in the chamber.

18       *Titration protocol 2*

19       This titration protocol was necessary for determination of coupling control of electrons  
20       through CI.

- 21       •  $L_N$  - malate (2 mM) and pyruvate (5 mM)
- 22       •  $P_{CI}$  - ADP (5 mM)
- 23       • Internal control for mitochondrial outer membrane integrity - cytochrome c (10  $\mu$ M);  
24       There was no indication of mitochondrial damage in the measurements included in  
25       the study as demonstrated by the 0.3%, 1.3%, 0.1%, -0.3%, 4.3%, and -0.1% change  
26       in mouse young and mature QUAD, SOL, and GAST respiration, respectively.

- 1 • ETS - FCCP; 0.5  $\mu$ M per addition up to optimum concentrations ranging from 1.5–3
- 2  $\mu$ M)
- 3 • CI inhibition - rotenone (0.5  $\mu$ M)
- 4 • ROX - antimycin A (2.5  $\mu$ M)

### 6 *Titration protocol 3*

7 This titration protocol was necessary for determination of coupling control of electrons  
8 through CII.

- 9 • CI inhibition - rotenone (0.5  $\mu$ M)
- 10 •  $L_N$  - succinate (10 mM)
- 11 •  $P_{CII}$  - ADP (5 mM)
- 12 • Internal control for mitochondrial outer membrane integrity - cytochrome c (10  $\mu$ M);
- 13 There was no indication of mitochondrial damage in the measurements included in
- 14 the study as demonstrated by the 7.3%, 2.6%, 9.8%, 13.4%, 5.1%, and 7.3% change
- 15 in mouse young and mature QUAD, SOL, and GAST respiration, respectively.
- 16 • ETS - FCCP; 0.5  $\mu$ M per addition up to optimum concentrations ranging from 1.5–3
- 17  $\mu$ M)
- 18 • ROX - antimycin A (2.5  $\mu$ M)

19  
20 Respiriometric values representing  $P_{CI}$  and  $P_{CII}$  did not differ across titration protocols.  
21 Consequently all  $P_{CI}$  and  $P_{CII}$  values achieved with the titration protocols for 2 and 3,  
22 respectively, were grouped with complementing respiratory state from titration protocol 1.

### 25 *Data analysis*

26 All mass-specific respirometric values were controlled to account for the differences in  
27 mitochondrial content, as indicated by CII protein expression, across age and fiber types. In

1     doing so all CII protein expression data was adjusted to a value of 1. The degree by which the  
2     protein expression had to be adjusted to equal 1 was then applied to all mass-specific  
3     respirometric values corresponding with the appropriate age and skeletal muscle type,  
4     respectively. Values of  $P_{CI}$  controlling for CI protein expression,  $P_{ETF}$  controlling for HAD  
5     protein expression, and  $P$  controlling for CIII protein expression all were also adjusted using  
6     the same method.

8     For all statistical evaluations, a p-value of  $< 0.05$  was considered significant. Differences in  
9     respiratory capacities and protein expression with age and across skeletal muscle groups were  
10    initially compared using a two-way ANOVA. When an ANOVA was significant, differences  
11    in respiratory capacities and protein expression with age and across skeletal muscle groups  
12    were evaluated using pairwise comparisons with a Bonferroni adjustment (SPSS Statistics  
13    17.0, SPSS, Inc. Chicago, IL, USA). Indices of mitochondrial efficiency did not express a  
14    Gaussian distribution and therefore a Kruskal-Wallis ANOVA and the U-Mann Whitney tests  
15    were used to reveal differences between between younger and older muscle as well as  
16    comparisons across muscle groups within the respective age groups.

## Results

### *Skeletal muscle protein expression*

As shown in Fig. 1, protein expression for all mitochondrial enzymes was greatest in the slow-twitch SOL muscle. In young animals only the expression of CII and CIV differed between QUAD and GAST, both of which were lost with age. Only SOL expressed a change in mitochondrial protein content with age as CI, CII, and CV all increased (Fig 1A, 1B, and 1E, respectively). Though no significant changes in protein expression of CIII (Fig. 1C) or mitochondrial complex IV (CIV; Fig. 1D) were apparent, both complexes showed a tendency to diminish with age in GAST ( $p = 0.060$  and  $0.063$ , respectively). Collectively this analysis illustrates that the protein content for enzymes involved in mitochondrial oxidative phosphorylation is largely unaffected in primarily fast-twitch glycolytic muscle (QUAD and GAST) but slightly increased in primarily slow-twitch oxidative muscle (SOL) with age.

### *Mitochondrial respiration*

Main effects of age on mass-specific respiration ( $\text{pmol O}_2 \text{ min}^{-1} \text{ mg ww}^{-1}$ ) were observed for  $P_{\text{ETF}}$  ( $p = 0.011$ ) and  $P_{\text{CII}}$  ( $p = 0.008$ ). This was reflected by the higher  $P_{\text{ETF}}$  and  $P_{\text{CII}}$  in mature QUAD ( $p = 0.031$  and  $0.037$ , respectively; Figure 2E) and GAST ( $p = 0.011$  and  $0.016$ , respectively; Figure 2I) versus their younger counterparts. There was also a main effect of muscle type on mass-specific respiration as SOL has greater respiration across all states compared to both QUAD and GAST ( $p < 0.001$ ).

Mass-specific respiration does not take into account differences in mitochondrial content between samples (Fig 1). Accordingly, all respirometric analyses were adjusted for CII protein content, a biomarker shown to express the best concordance with mitochondrial

1 content and total cristae area as measured by transmission electron microscopy as well as  
2 myocellular respiratory capacity over protein concentrations for all other mitochondrial  
3 complexes (80). When controlling respiration to mitochondrial content the main effect of age  
4 on respiration capacity ( $\text{pmol O}_2 \text{ min}^{-1} \text{ CI}^{-1}$ ) appeared to be silenced by the divergent  
5 fluctuations in mitochondrial function across skeletal muscle types in response to age.  
6 Respiratory states representing  $P_{\text{CI}}$ ,  $P$ , and ETS in QUAD and  $P_{\text{CI}}$ ,  $P$ , ETS, and  $P_{\text{CII}}$  in SOL all  
7 lost respiratory capacity in response to age (Figures 2F and 2H). Conversely, GAST increased  
8 respiratory capacity at every respiratory state measured (Figure 2J) in response to age. The  
9 differences in respiratory capacity when controlling for mitochondrial content across skeletal  
10 muscle in younger and older mice is shown on Fig. 2B and 2D, respectively.

11  
12 *Respiratory capacity and coupling control specific to mitochondrial complexes I & III*

13 Electron transport and control specifically through CI and CIII are of particular interest as  
14 ROS production at each respective complex accounts for the majority of mitochondria-  
15 specific oxidant production (9-14). In order to isolate analysis to these specific complexes, all  
16  $P_{\text{CI}}$  values, including respirometric values from both titration protocols 1 and 2, and maximal  
17 state 3 respirometric values,  $P$ , were adjusted to account for the differences in CI and CII  
18 protein expression, respectively, with age and across muscle groups (Fig. 1B & D).

19  
20 There were main effects of age ( $p = 0.001$ ) on  $P_{\text{CI}}$  respiration when controlling for CI  
21 expression ( $\text{pmol O}_2 \text{ min}^{-1} \text{ CI}^{-1}$ ), which increased with age in both QUAD and GAST ( $p <$   
22  $0.001$ ) and decreased in SOL ( $p = 0.003$ ; Figures 3A-C). The coupling efficiency during  $P_{\text{CI}}$   
23 respiration deteriorated with age in GAST ( $p = 0.043$ ) and showed a tendency to diminish in  
24 QUAD as well ( $p = 0.085$ ; Table 2). Though no differences in respiratory capacity were  
25 observed across all young muscle groups during  $P_{\text{CI}}$  when controlling for CI, the coupling  
26 control was superior in young QUAD and GAST over SOL ( $p = 0.021$  and  $0.009$ ,  
27 respectively). In the older muscle both QUAD and GAST presented with higher  $P_{\text{CI}}$  than SOL

( $p < 0.001$ ) and both, again, expressed a tighter coupling efficiency than SOL ( $p = 0.004$  and  $p < 0.001$ ).

There were also main effects of age ( $p = 0.009$ ) on maximal state 3 respiration and oxidative phosphorylation capacity,  $P$ , when controlling for CIII protein expression ( $\text{pmol O}_2 \text{ min}^{-1} \text{ CIII}^{-1}$ ). Respiration capacity in both QUAD and GAST increased with age ( $p = 0.009$  and  $0.001$ , respectively) while SOL did not change ( $p = 0.144$ ). Differences across young muscle groups were evident between both QUAD and SOL versus GAST ( $p = 0.023$  and  $0.001$ , respectively) and across mature muscle groups with QUAD greater than SOL ( $p = 0.020$ ).

#### *Respiratory capacity and control specific to $\beta$ -oxidation*

Only values of fatty acid oxidative capacity,  $P_{\text{ETF}}$ , were adjusted to account for the differences in HAD protein expression (Figure 1D).  $P_{\text{ETF}}$  ( $\text{pmol O}_2 \text{ min}^{-1} \text{ HAD}^{-1}$ ) increased with age in QUAD ( $p = 0.004$ ) and showed a tendency to increase in GAST ( $p = 0.065$ ). Differences across young and mature muscle groups were evident with both QUAD and GAST far below SOL ( $p < 0.001$ ). Though  $P_{\text{ETF}}$ , when controlling for HAD, did not change in SOL, the coupling efficiency during  $\beta$ -oxidation diminished with age. Despite this decrease with age, the coupling control of electron transport during  $\beta$ -oxidation in SOL was significantly better in younger and older QUAD ( $p = 0.01$  and  $0.05$ , respectively). Coupling control during fat oxidation did not change with age in QUAD or GAST, though it did differ between young SOL and GAST ( $p = 0.05$ ). This difference was lost with age (Table 2).

**Discussion**

The aim of this study was to analyze the effect of biological aging on respiratory capacities and mitochondrial coupling control across different skeletal muscle types as a function of age. Our main findings are: 1.) Mitochondrial function is dependent on skeletal muscle type, irrespective of age; 2.) Submaximal state 3 respiration specific to mitochondrial complex I,  $P_{CI}$ , increased in both QUAD and GAST but decreased in SOL when controlling for complex I protein expression; 3.) Coupling control during  $P_{CI}$  was also lost with age in GAST and indicated a tendency for deterioration in QUAD but remained unchanged in SOL; 4.) Maximal state 3 respiration and oxidative phosphorylation capacity,  $P$ , increased with age in QUAD and GAST but not SOL when controlling for mitochondrial complex III protein expression; and finally 5.) While the capacity for fat respiration increased with age in QUAD when controlling for differences in 3-hydroxyacyl coenzyme a dehydrogenase (HAD) protein expression across skeletal muscle types, the coupling control during fat oxidation worsened with age only in SOL.

*Variations in mitochondrial function across fiber types*

There is some dispute on whether or not differences in respiratory capacity fluctuate across different skeletal muscle types that vary in their biochemical make-up, tailoring oxidative function to specific metabolic demand (81). Initial reports suggested that respiratory differences could be accounted for simply by the differences in mitochondrial content (50, 82). This has since been refuted as various skeletal muscles have been shown to express respiratory differences across muscle types (46, 47, 83, 84). We recently substantiated these differences in mitochondrial function across muscle types as respiration capacities in both

GAST and QUAD were greater than those in SOL at  $P_{CL}$ ,  $P_{CII}$ , P, and ETS respiratory states when normalizing mass-specific respiration to citrate synthase activity (85). While it seems evident that differences in function exist across different skeletal muscle fiber types, even when controlling for the disproportionate expression of mitochondria, the data presented here demonstrate how important normalization of the mass-specific respirometric values can be to overall data interpretation.

Our findings specific to mitochondrial protein expression are contrary to studies suggestive of a progressive loss of mitochondria with age (34, 48). We cannot exclude the possibility that some mitochondrial protein/fragments may have been lost as a result of our homogenization and centrifugation procedures. Thus we cannot confirm that our mitochondrial protein determination is representative of the total per volume of muscle mass, possibly explaining the differences between studies. Alternatively, however, our results are in accordance with several studies reporting negligible to minor changes in mitochondrial protein expression with age, including an increase of expression dependent on skeletal muscle type (32, 33, 45, 86). There is also evidence in mice of increased skeletal muscle mitochondrial protein synthesis with advancing age (86). Although it is unlikely that the preferential loss of mitochondrial protein during homogenization and centrifugation procedures biased our results, we cannot definitively exclude this possibility.

*Skeletal muscle mitochondrial respiratory capacity and control across skeletal muscle types with age*

Mitochondrial respiratory capacities across several different states diminished with age in QUAD and SOL (Fig. 2F & H). These results coincide with previous reports where oxidative capacity is reported to decline with age in either quadriceps or mixed muscle homogenates (19, 31, 33, 35, 36, 38, 39). Alternatively, mitochondrial respiratory capacities across all states increased with age in GAST (Figure 2J). The increase in respiratory capacity with age in GAST also corresponds with previous work that demonstrated a greater reliance with age of

1 oxidative phosphorylation for ATP synthesis in primarily type 2 fast twitch glycolytic skeletal  
2 muscle (41, 42, 87).  
3  
4 Mitochondria serve as a primary source of *in vivo* oxidant production (2-5) with the primary  
5 oxidant production occurring at CI (6-8) and CIII (9-14). Despite the macro decreases in  
6 mitochondrial specific respiratory capacity in QUAD (Fig. 2F), respiration and electron flow  
7 specifically through CI and CIII increased (Fig. 3A & 4A). Coupling control during  $P_{CI}$  also  
8 had a tendency to deteriorate in QUAD ( $p = 0.085$ ) in response to age (Table 2). Respiration  
9 and electron flow specifically through CI and CIII also increased in GAST, while coupling  
10 control during  $P_{CI}$  worsened with age (Table 2). Electron coupling control is indicative of  
11 oxidant production as mitochondrial production of superoxide is closely related to  
12 mitochondrial coupling efficiency during respiration (9). Moreover, increased mitochondrial  
13 respiration capacity also results in increased oxidative damage and shorter lifespan (27).  
14 Respiratory capacity through CI diminished while capacity through CIII and electron  
15 coupling control through CI remained unaffected by age in the slow twitch oxidative SOL  
16 (Fig 3B, 4B, and Table 2, respectively). Highly glycolytic skeletal muscle has been shown to  
17 have higher oxidant production with a reciprocal lower capacity for oxidant scavenging  
18 compared to highly oxidative muscle (88). Predominantly fast twitch skeletal muscle also  
19 have been reported to accrue age-associated oxidative damage, as assessed with protein  
20 carbonyl profiles across different skeletal muscle types, more rapidly than slow twitch  
21 oxidative muscle (89). Collectively the results from this study, in corroboration with these  
22 previous findings, provide the direct evidence of a predisposition to electron transport system  
23 dysfunction with age in type 2 fast twitch glycolytic skeletal muscle that is not observed in  
24 type 1 slow twitch oxidative muscle and has been previously suggested in humans using  
25 indirect metabolic imaging techniques (46, 47). Preliminary evidence suggests that caloric  
26 restriction (90) and exercise (91) reduce mitochondrial oxidant production and may serve to  
27 counterbalance these age-related impairments in electron transport.  
28

1 Ratios of coupling control are based on the supposition that a tightly coupled system can be  
2 distinguished from a dyscoupled system by the magnitude of difference between two steady  
3 respiratory states with identical substrate supply (92). We used leak control ratios as our  
4 indices of mitochondrial coupling control efficiency (Table 2). Leak control ratios are  
5 produced between two reciprocal respiratory states; a low flux state (i.e.  $L_N$  with malate and  
6 pyruvate, state 4 respiration) compared to an equivalent high respiratory flux state (i.e.  $P_{CI}$ ,  
7 submaximal state 3 respiration). An identical substrate supply is necessary to pair  
8 corresponding states. Flux control ratios demonstrate coupling efficiency using a theoretical  
9 minimum of 0.0, which indicates a fully coupled system, to a value of 1.0 representing a fully  
10 non-coupled or dyscoupled system (63). While we show evidence of a loss of coupling  
11 control with aging during  $P_{CI}$  in GAST and a tendency in QUAD, unfortunately coupling  
12 efficiency during maximal state 3 respiration could not be determined with the titration  
13 protocols utilized as there was no reciprocal leak state measured for P.

#### 14 *Respiratory capacity and control of fat oxidation with aging*

15 We found that the capacity for fat respiration increased with age without a reciprocal loss of  
16 coupling efficiency during  $\beta$ -oxidation in QUAD when controlling for differences in HAD  
17 protein expression. Conversely, capacity for fat respiration was unaltered with age in SOL,  
18 though the coupling control during fat oxidation diminished. Neither respiratory capacity nor  
19 control of fat oxidation was altered in GAST. Skeletal muscle intramyocellular lipid (IMCL)  
20 stores increase in parallel with age-related decreases in mitochondria (37). Moreover, IMCL  
21 content is also reported to drift away from the mitochondrial reticulum with age (37). The  
22 dysregulation of fat metabolism within skeletal muscle is associated with the development of  
23 insulin resistance and metabolic disease (93-95). The loss of mitochondrial coupling  
24 efficiency in type I slow twitch fibers, such as observed here, may in part explain the reported  
25 insulin resistance in healthy, lean, elderly subjects (38). This is of interest in regards to  
26 metabolic disease as well as aging and merits further investigation.

1     *Conclusion*

2     Here we directly demonstrate impairments of mitochondrial function in response to aging in  
3     skeletal muscle. The specific age-induced alteration in function is dependent on skeletal  
4     muscle type. Skeletal muscle composed primarily of type 2 fast twitch glycolytic fibers are  
5     predisposed to progressive impairments in mitochondrial function with age as type I slow  
6     twitch oxidative fibers appear to protect against this effect.

**FIGURE LEGENDS**

**Figure 1. Protein expression of mitochondrial complexes and proteins with age.**

Skeletal muscle protein expression determined in young (10-12 wks) and mature (74-76 wks) C57Bl/6 mice. Protein expression for (A) CI, mitochondrial complex I or NADH dehydrogenase; (B) CII, mitochondrial complex II or succinate dehydrogenase; (C) CIII, mitochondrial complex III or cytochrome *bc<sub>L</sub>* complex; (D) CIV, mitochondrial complex IV or cytochrome c oxidase; (E) CV, mitochondrial complex V or ATP Synthase; and (F) HAD, 3-hydroxyacyl coenzyme a dehydrogenase, is illustrated in response to age and across skeletal muscles. Example blots for one analysis from one animal are shown above the graph. Values are means  $\pm$  SD. a indicates significant difference in age within a skeletal muscle,  $p < 0.05$ ; b shows significant difference between soleus (black) from both quadricep (grey) and lateral gastrocnemius (white) within the same age,  $p < 0.05$ ; and c indicates differences between quadricep and gastrocnemius within the same age,  $p < 0.05$ .

**Figure 2. Skeletal muscle respirometric analysis.** Mass-specific respiration across muscle groups in (A) young and (C) mature animals. Mass-specific respiration with age in mouse (E) quadricep, (G) soleus, and (I) gastrocnemius skeletal muscles. Mitochondrial-specific respiration controlling for mitochondrial content, as assessed by mitochondrial complex II protein expression (80), across skeletal muscles in (B) young and (D) mature animals. Mitochondrial-specific respiration with age in mouse

(F) quadricep, (H) soleus, and (J) gastrocnemius skeletal muscles.  $L_N$ , leak respiration without adenylates;  $P_{EFT}$ , maximal fatty acid oxidation;  $P_{CI}$ , submaximal state 3 respiration through mitochondrial complex I (CI);  $P$ , maximal state 3 respiration – oxidative phosphorylation capacity; Cyt C, cytochrome c, internal test of mitochondrial membrane integrity; ETS, electron transport system capacity; and  $P_{CII}$ , submaximal state 3 respiration through mitochondrial complex II (CII). Data presented as mean  $\pm$  SD. \*, \*\*, \*\*\* indicates significant difference of  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq 0.001$ , respectively.

**Figure 3. Respiratory capacity and control through mitochondrial complex I (CI).** Submaximal state 3 respiratory capacity specific to CI ( $P_{CI}$ ) when controlling for CI protein expression with age in (A) quadricep, (B) soleus, and (C) gastrocnemius skeletal muscles. \*, \*\*, \*\*\* indicates significant difference of age,  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq 0.001$ , respectively.

**Figure 4. Respiratory capacity and control through mitochondrial complex III (CIII).** Maximal state 3 respiration and oxidative phosphorylation capacity ( $P$ ) when controlling for CIII protein expression with age in (A) quadricep, (B) soleus, and (C) gastrocnemius skeletal muscles. \*, \*\*, \*\*\* indicates significant difference of age,  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq 0.001$ , respectively.

**Figure 5. Respiratory capacity and control through electron transferring flavoprotein (ETF) during maximal fat respiration.** Submaximal state 3 respiratory capacity specific to the capacity for fat oxidation and electron transfer through ETF ( $P_{ETF}$ ) when controlling for 3-hydroxyacyl coenzyme a dehydrogenase (HAD) protein

1 expression with age in (A) quadricep, (B) soleus, and (C) gastrocnemius skeletal  
2 muscles. \*, \*\*, \*\*\* indicates significant difference of age,  $p \leq 0.05$ ,  $p \leq 0.01$ , and  $p \leq$   
3 0.001, respectively. # indicates a tendency of a difference with age,  $p = 0.065$ .
